| CHAPTER I The World of Life Science | • | |

BEFORE YOU READ

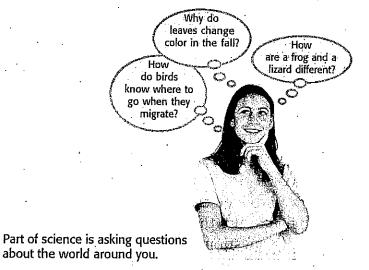

After you read this section, you should be able to answer these questions:

- What is life science?
- Why is life science important for everyday life?

What Is Life Science?

Imagine that it is summer. You are lying on the grass in a park watching dogs play and bees visiting flowers. An ant carries away a crumb from your lunch. Suddenly, questions pop into your head: How do ants find food? Why don't bees visit every flower? Why do dogs play? By asking these question, you are thinking like a life scientist.

Life science is the study of living things. Asking questions about the world around you is the first step in any scientific investigation. ✓

What Questions Do Life Scientists Ask?

Take a look around your home or neighborhood. Just about anywhere you go, you will find some kind of living thing. The world around us is full of an amazing diversity of life. Single-celled algae, giant redwood trees, and 40-ton whales are all living things. For any living thing, you can ask: How does it get its food? Where does it live? How does it behave? Life scientists ask questions like these to learn about the world.

SECTION 1 Asking About Life continued

Who Is a Life Scientist?

A life scientist is anyone who studies organisms, or living things. The women and men who are life scientists can live and work anywhere in the world. Some life scientists work on farms. Others study organisms in forests or in oceans. Some even work in space!

Life scientists can study many different features of organisms. They may study how organisms behave and how organisms affect their environments. Some life scientists study how organisms change with time and how they pass on their features to their young. Some life scientists even study organisms that lived millions of years ago.

CHAPTER 1 The World of Life Science

Scientific Methods

BEFORE YOU READ

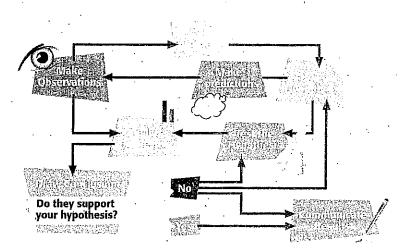

After you read this section, you should be able to answer these questions:

- What are scientific methods?
- What is a hypothesis?
- How do scientists test a hypothesis?

What Are Scientific Methods?

A group of students in Minnesota went on a field trip to a wildlife refuge. They noticed that some of the frogs they saw looked strange. For example, some of the frogs had too many legs or eyes. The frogs were deformed. The students wondered what made the frogs deformed. They decided to carry out an investigation to learn what happened to the frogs.

By making observations and asking questions about them, the students were using scientific methods. Scientific methods are a series of steps that scientists use to answer questions and to solve problems. The figure below shows the steps in scientific methods.

As you can see, the order of steps in scientific methods can vary. Scientists may use all of the steps or just some of the steps during a certain investigation. They may even repeat some of the steps. The order depends on what works best to answer a certain question.

Outline As you read this section, make a chart showing the different steps in scientific methods. In the chart, describe how the students in Minnesota used each step to investigate the deformed frogs.

Critical Thinking

4. Explain Why is it important for observations to be accurate?

TAKE A LOOK

5. Identify Give three kinds of observations that can be made with the tools in the picture.

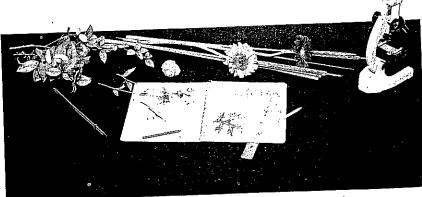

VVIIV IS IL IIII

Asking a question helps scientists focus their research on the most important things they want to learn. In many cases, an observation leads to a question. For example, the students in Minnesota observed that some of the frogs were deformed. Then they asked the question, "Why are some of the frogs deformed?" Answering questions often involves making more observations.

How Do Scientists Make Observations?

The students in Minnesotá made careful observations to help them answer their question. The students caught many frogs. Then they counted how many normal and deformed frogs they caught. They photographed, measured, and described each frog. They also tested the water the frogs were living in. The students were careful to record their observations accurately.

Like the students, scientists make many different kinds of observations. They may measure length, volume, time, or speed. They may describe the color or shape of an organism. They may also describe how an organism behaves. When scientists make and record their observations, they are careful to be accurate. Observations are useful only if they are accurate.

Scientists use many different tools, such as microscopes, rulers, and thermometers, to make observations.

SECTION 2 Scientific Methods continued

What Is a Hypothesis?

After asking questions and making observations, scientists may form a hypothesis. A hypothesis (plural, hypotheses) is a possible answer to a question. A good hypothesis is based on observations and can be tested. When scientists form a hypothesis, they base it on all of the observations and information that they have.

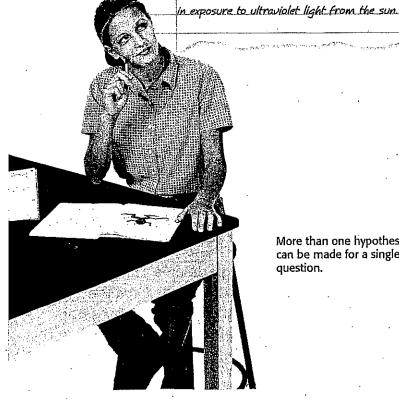

A single question can lead to more than one hypothesis. The students in Minnesota learned about different things that can cause frogs to be deformed. They used this information to form three hypotheses to answer their question. These hypotheses are shown in the figure below.

SECTION 2 Scientific Methods continued

How Do Scientists Test a Hypothesis?

Scientists perform experiments to show whether a certain factor caused an observation. A *factor* is anything in an experiment that can change the experiment's results. Some examples of factors are temperature, the type of organism being studied, and the weather in an area.

To study the effect of each factor, scientists perform controlled experiments. A **controlled experiment** tests only one factor at a time. These experiments have a control group and one or more experimental groups.

The factors for the control group and the experimental groups are the same, except for the one factor being tested. This factor is called the **variable**. The variable is different in each experimental group. Any difference in the results between the control and experimental groups is probably caused by the variable.

DESIGNING AN EXPERIMENT

Experiments must be carefully planned. Every factor should be considered when designing an experiment. It is also important for scientists to use ethical guidelines when they design and carry out experiments. These guidelines help to make sure that the scientists do not cause unnecessary harm to the organisms in the experiment.

The table below shows an experiment to test whether UV light can cause frogs to be deformed. This experiment has one control group and two experimental groups. All the factors between these groups are the same except the amount of UV light exposure. The control group receives no UV light. The number of days that the frog eggs are exposed to UV light is different between the experimental groups. Therefore, exposure to UV light is the variable.

| | | Control Factors | | | Variable | |

SECTION 2 Scientific Methods continued

READING CHECK

13. Explain Why do

scientists try to use many individuals in their

experiments?

COLLECTING DATA

Scientists often try to test many individuals. For example, in the UV light experiment, a total of 300 frogs were tested. By testing many individuals, scientists can account for the effects of normal differences between individuals in each group. They can be more certain that differences between the control and experimental groups are caused by the variable. abla

Scientists will often repeat an experiment to determine if it produces the same results every time. If an experiment produces the same results again and again, scientists can be more certain that the results are true.

The figure below shows the setup of the UV light experiment. It also shows the results of the experiment.

| | Experimenta | l Groups |
|---|---|--|
| Control Group Group #1 No UV light exposure | Group #2 UV light exposure for 15 days | Group #3 UV light exposure for 24 days |
| ත | <u>०० ६० १५ ७</u> | 0 0000000 |

| 50 | | | |
| <u> </u> | • | . • | |
| ğ | • | | |
| quin | | ٠ | |
| Ž | | | |

How Do Scientists Analyze Results?

When scientists finish an experiment, they must analyze the results. The information they collect during the analysis helps them explain their observations.

To organize their data, scientists often make tables and graphs. Scientists study the organized data to learn how the variable affected the experiment. The data from the UV light experiment is shown in the table below. This table shows that frogs that were exposed to 24 days of UV light developed deformities.

| Number of days of UV exposure | Number of deformed frogs |
|-------------------------------|--------------------------|
| 0 | 0 |
| 15 | 0 |
| 24 | 48 |

| Name | Class | Date |
|--|-------|------|
| SECTION 2 Scientific Methods continued | | |

What Are Conclusions?

After analyzing results from experiments, scientists must decide if the results support the hypotheses. This is called *drawing conclusions*. Finding out that a hypothesis is not true can be as valuable as finding out that a hypothesis is true.

Sometimes, the results do not support the hypothesis. When this happens, scientists may repeat the investigation to check for mistakes. Scientists may repeat experiments hundreds of times. Another option is to ask another question and make a new hypothesis.

The UV light experiment showed that UV light can cause frogs to be deformed. However, this does not mean that UV light definitely caused the frog deformities in Minnesota. Many other factors may affect the frogs. Some of these factors may be things that scientists have not even thought of yet.

Questions as complicated as the deformed frogs are rarely solved with a single experiment. The search for a solution may continue for many years. Finding an answer doesn't always end an investigation. In many cases, the answer begins another investigation. In this way, scientists continue to build knowledge.

Why Do Scientists Share Their Results?

After finishing a study, scientists share their results with others. They write reports and give presentations. They can also put their results on the Internet.

Sharing information allows others the chance to repeat the experiments for themselves. Data from new experiments can either support the original hypothesis, or show that it needs to be changed.

Communicating the results of experiments is an important step in scientific methods.

Scientific Models

Scientific Models

BEFORE YOU READ

After you read this section, you should be able to answer these questions:

- How do scientists use models?
- What are scientific theories and laws?

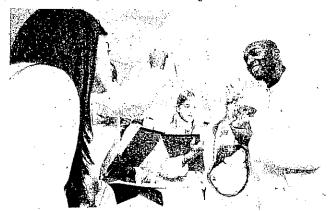

What Are Models?

You need a microscope to see inside most cells. How can you learn about the parts of a cell if you don't have a microscope? One way is to use a model. Scientists use models to learn about things that they cannot see or touch.

A model is something scientists use to represent an object or event to make it easier to study. Scientists study models to learn how things work or are made in the natural world. However, you cannot learn everything by studying a model, because models are not exactly like the objects they represent. Some types of scientific models are physical models, mathematical models, and conceptual models.

PHYSICAL MODELS

A toy rocket and a plastic skeleton are examples of physical models. *Physical models* are models that you can see or touch. Many physical models look like the things they represent. The figure shows students using a model of a human body to learn how the body works. However, because the model is not alive, the students cannot learn exactly how the body functions.

STUDY TIP

Learn New Words As you read, underline words you don't know. When you figure out what they mean, write the words and their definitions in your notebook.

| READIN | G CHE | СК |

SECTION 3 Scientific Models continued

MATHEMATICAL MODELS

A mathematical model is made up of mathematical equations and data. Some mathematical models are simple. For example, a Punnett square is a model of how the traits of parents can be combined in their offspring. Using this model, scientists can predict how often certain traits will appear in the offspring of certain parents.

Scientists use Punnett squares to predict the features of living things.

Math Focus

3. Calculate What percentage of the offspring in the figure are round?

> Some mathematical models are more complicated than the Punnett square. Scientists may use computers to help them interpret more complicated models. Computers work faster and make fewer mistakes than people do.

CONCEPTUAL MODELS

A conceptual model is a description of how something works or is put together. Some conceptual models represent ideas. Others connect things that we know to things that we are unfamiliar with. For example, scientists use conceptual models to classify the ways that animals behave. Scientists can use these models to predict how an animal will act in a certain situation.

WHY SCIENTISTS USE MODELS

Scientists use models to study things that are too difficult or dangerous to study in real life. Scientists use models to study very small things, such as atoms, or very large things, such as the Earth. Some scientists use models to predict things that haven't happened yet, or to study events that happened long ago. For example, scientists use computers to produce models of dinosaurs. These models can show how dinosaurs may have looked and moved.

How Does Scientific Knowledge Grow?

Science is always changing. Two scientists can study the same data and make different conclusions. When new technology is developed, scientists often review old data and come to new conclusions. By observing patterns in the world, scientists can create scientific theories and laws.

A scientific **theory** is a scientific explanation that connects and explains many observations. Scientific theories are based on observations. They explain all of the observations about a topic that scientists have at a certain time. Theories are conceptual models that help organize scientific thinking. They are used to explain and predict situations.

A scientific **law** is a statement or equation that can predict what will happen in certain situations. Unlike theories, scientific laws do not explain why something happens. They only predict what will happen. Many people think that scientific theories become scientific laws, but this is not true. Actually, many scientific laws provide evidence to support scientific theories.

How Do Scientific Ideas Change?

Scientists are always discovering new information. This new information may show that a theory is incorrect. When this happens, the theory must be changed so that it explains the new information. Sometimes, scientists have to develop a totally new theory to explain the new and old information.

Sometimes, more than one new theory is given to explain the new information. How do scientists know that a new theory is accurate? They use scientific methods to test the new theory. They also examine all the evidence to see if it supports the new theory. Scientists accept a new theory when many tests and pieces of evidence support it.

Investigate Use the Internet or the library to learn about a scientific idea that interests you. Study how the idea has changed with time. Share your findings with your class.

CHAPTER 1 The World of Life Science

SECTION 4

Tools, Measurement, and Safety

BEFORE YOU READ

After you read this section, you should be able to answer these questions:

- How do tools help scientists?
- How do scientists measure length, area, mass, volume, and temperature?

What Tools Do Scientists Use?

Scientists can use technology to find information and to solve problems. **Technology** is the application of science for practical purposes. New technology can allow scientists to get information that was not available before.

CALCULATORS AND COMPUTERS

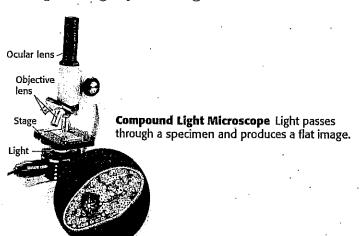

Scientists analyze, or examine, data using many different tools. Computers and calculators can help scientists do calculations quickly. Computers are also very important tools for collecting, storing, and studying data.

COMPOUND LIGHT MICROSCOPES

Scientists use microscopes to see things that are very small. One kind of microscope is a compound light microscope is a tool that magnifies small objects. It has three main parts: a stage, a tube with two or more lenses, and a light. Items are placed on the stage. Light passes through them. The lenses help to magnify the image.

Compare As you read this section, make a table comparing how scientists measure length, area, mass, volume, and temperature. Include the tools and units that scientists use for each type of measurement.

TAKE A LOOK

1. Identify What are the three main parts of a compound light microscope?

18

It is important to learn the SI units that are used for different types of measurements. You will use SI units when you make measurements in the science lab. SECTION 4 Tools, Measurement, and Safety continued

LENGTH

Length is a measure of how long an object is. The SI unit for length is the meter (m). Centimeters (cm) and millimeters (mm) are used to measure small distances. There are 100 cm in 1 m. There are 1,000 mm in 1 m. Micrometers (µm) are used to measure things that are very small, such as cells. There are 1 million µm in 1 m. Rulers and metersticks are used to measure length.

| Length tools: ruler or meterstick | SI Unit: meter (m) kilometer (km) centimeter (cm) millimeter (mm) | 1 km = 1,000 m 1 cm = 0.01 m 1 mm = 0.001 m 1 µm = 0.000001 m |
|---|--|--|
|---|--|--|

TAKE A LOOK

4. Identify What is the SI unit for length?

AREA

Area is a measure of how much surface an object has. For most objects, area is calculated by multiplying two lengths together. For example, you can find the area of a rectangle by multiplying its length by its width. Area is measured in square units, like square meters (m²) or square centimeters (cm²). There are 10,000 cm² in 1 m².

There is no tool that is used to measure area directly. However, you can use a ruler to measure length and width. Multiply these measurements to find area.

| Area . | square meter (m²) | $1 \text{ cm}^2 = 0.0001 \text{ m}^2$ |
|------------------|-------------------------|---------------------------------------|
| tool: ruler (to | square centimeter (cm²) | , |
| measure lengths) | , ` . <i>`</i> . | · |

READING CHECK

5. Explain How can you find the area of a rectangle?

VOLUME

Volume is the amount of space an object takes up. You can find the volume of a box-shaped object by multiplying its length, width, and height together. You can find the volume of objects with many sides by measuring how much liquid they can push out of a container, as shown in the figure on the next page. You can measure the volume of a liquid using a beaker or a graduated cylinder.

Volume is often measured in cubic units. For example, very large objects can be measured in cubic meters (m³). Smaller objects can be measured in cubic centimeters (cm³). There are 1 million cm³ in 1 m³. The volume of a liquid is sometimes given in units of liters (L) or milliliters (mL). One mL has the same volume as one cm³. There are 1,000 mL in 1 L. There are 1,000 L in one m³.

| tools: graduated cubic centimeter (cm³) 1 L = | = 0.000001 m ³ = 0.001 m ³ = 1 cm ³ |

| | Second 1 | |
| volume of rock = 80 mL | 70 mL = 10 mL // | |
| VOID TO THE STATE OF THE STATE | | |
| | n the cylinder on up to 80 m | ıL. |

The rock made the volume of material in the cylinder go up to 80 mL. The rock pushed 10 mL of liquid out of the way. The volume of the rock is 10 mL. Because 1 mL = 1 cm³, the volume of the rock can also be written as 10 cm3.

MASS

Mass is a measurement of the amount of matter in an object. The SI unit for mass is the kilogram (kg). The masses of large objects, such as people, are measured using kg. The masses of smaller objects, such as an apple, are measured in grams (g) or milligrams (mg). There are 1,000 g in 1 kg. There are 1 million mg in 1 kg. Balances are used to measure mass.

Math Focus

8. Convert How many mg are there in 1 g? :

| | • | |
|-----------------------|--|--------------------------------------|
| Mass tool: balance | SI Unit: kilogram (kg) gram (g) milligram (mg) | 1 g = 0.001 kg 1 mg = 0.000001 kg |

| Name | Class | Date _ | |
|--|-----------|--------|--|
| SECTION 4 Tools, Measurement, and Safety | continued | | |

TEMPERATURE

Temperature is a measure of how hot or cold an object is. The SI unit for temperature is the Kelvin (K). However, most people are more familiar with other units of temperature. For example, most people in the United States measure temperatures using degrees Fahrenheit (°F). Scientists often measure temperatures using degrees Celsius (°C). Thermometers are used to measure temperature. ✓

| Temperature tool: thermometer SI Unit: kelvin (K) degrees Celsius (°C) | 0°C = 273·K 100°C = 373 K |
|--|------------------------------|
|--|------------------------------|

It is easy to change measurements in °C to K. To change a temperature measurement from °C to K, you simply add 273 to the measurement. For example, 200 °C = 200 + 273 = 473 K. It is more complicated to change measurements in K or °C into °F. That is why scientists do not measure temperatures in °F. \checkmark

How Can You Stay Safe in Science Class?

Science can be exciting, but it can also be dangerous. In order to stay safe while you are doing a science activity, you should always follow your teacher's directions. Read and follow the lab directions carefully, and do not take "shortcuts." Pay attention to safety symbols, such as the ones in the figure below. If you do not understand something that you see in a science activity, ask your teacher for help.

Safety Symbols
